If you can't use Acrobat XI Professional because it's too expensive, you can use Acrobat XI Lite, which offers most of the features of the Standard version. Get it for Windows, iOS, or Android. In many engineering designs, components such as motor vehicles, machinery and other equipment may require strict dimensional tolerances on machined parts to reduce the probability of product failure. Machined parts are typically formed of metal or plastic and have both cutting and scraping attributes. For example, products such as wind turbines typically require minimal scrap material. As a result, a number of important variables, such as the accuracy of the height of the machined parts, the depth of the cut, the contour of the machined parts, etc., are tightly controlled. In many applications, the machining of the parts may occur in the field. Therefore, the repeatability of the operation of the cutting or scraping equipment (e.g., robots) as it is used to machine parts becomes critical. The required cutting tolerances are typically very tight in order to ensure the quality of the final product. In some applications, however, such as when machines are involved in machining parts that must be entirely enclosed within an assembly, they must be wholly controlled from within the enclosure in order to preclude interference with the integrity of the

final product. For example, in the case of wind turbines, where the final product must be enclosed in an assembly that is bolted to the tower, the control of the grinding of the tip of the blade must be more strict than in the field. As it is not feasible to ground the tip of the blade in the field, in field certification environments, the so-called tip grinding must be entirely precluded from interference with the integrity of the final product. In these environments, the machining procedure must be wholly and completely controlled from within the certification or assembly environment. The difficulty in implementing such strict dimensional control is that there are many variables that must be controlled. For example, if one variable is out of tolerance, the remaining variables may require additional machining to adjust for the error. There is a need, therefore, for a machine that will accurately and repeatably machine parts such that the resulting final parts will meet their required tolerances. There is also a need for a method of controlling such a machine. 6d1f23a050
