I know the CAPM model is not entirely Bayesian, but I'm just wondering: If I understood correctly, the CAPM has 2 inputs/variables: expected return (risk-free rate) and the market beta coefficient. Shouldn't the model use the discount rate instead of risk-free rate as input? A: You have a few different questions in one. You are right in saying that the CAPM uses risk free rate r as the input. It does not however, have r as a proxy for

Y (the expected return on a stock). So it would not fit in your model in any case. The proxy is used as the beta and expected return, by using the following relationship. $$r=\frac{1-Y}{1+Y}$$ And you know the discount rate is the required input (although it is not usually included in the model). But that is because we use it to discount future cash flows (think of how much 1 today is worth in 1 year, in the example above this is simply $\frac12$ so $r=\frac12$). Finally, you note "if the model uses the discount rate instead of risk-free rate as the input, wouldn c6a93da74d
