Production of hydrocarbons usually takes place through a well-bore until sufficient hydrocarbons are produced to justify drilling a lateral borehole through the hydrocarbon deposit from the well-bore to a production zone. A problem with the production of hydrocarbons from some subterranean formations is that the formation is depleted in the area of the lateral borehole. When hydrocarbons are produced from the depleted formation, less oil is produced than is produced from the surrounding rock. It is not uncommon for the producing zone to be depleted in the lateral direction, for example, a well producing from an oil bearing reservoir in the Fruitdale formation which is depleted along the course of the well bore.
